Chapter 1

Overview

1.1 SGPC Architecture Overview

1.2 Registers

User-accessible Registers

Internal Registers

1.3 Instruction Conventions

Instruction Layout

Addressing Modes

1.4 Instruction Set

1.5 Interrupt Model

1.6 Memory Management Model

Chapter 2

Register Set

This chapter describes the registers seperated in four groups based on accessability. however, the internal registers are omitted from this chapter since these are implementation specific.

2.1 Foreground Registers

The foreground registers are the registers all regular instructions can read from and write to. There are eight 8-bit and eight 16-bit foreground registers. These registers are preserved in interrupts.

Table 2.1: List of Foreground Registers

ID	Mnonic	Descriptive Name	Length in bits
0x0	al	The lower byte of ax	8
0x1	ah	The higher byte of ax	8
0x2	bl	The lower byte of bx	8
0x3	bh	The higher byte of bx	8
0x4	cl	The lower byte of cx	8
0x5	ch	The higher byte of cx	8
0x6	dl	The lower byte of dx	8
0x7	dh	The higher byte of dx	8
0x8	ax	The first GPR	16
0x9	bx	The second GPR	16
0xA	cx	The third GPR	16
0xB	dx	The fourth GPR	16
0xC	ex	The fifth GPR	16
0xD	tm	Temporary data	16
0xE	sp	Stack pointer	16
0xF	pc	Program counter	16

General-Purpose Registers (GPRs)

These registers are meant for computing storage. The first four 16-bit registers are all splitted into two 8-bit registers. So software can directly access the upper and lower byte of these 16-bit registers.

Temporary Data Register

This registers is meant to facilitate call procedures. So it won't be preserved in a function call. However this nothing more than a suggestion to the user, software can use this register as a regular GPR.

Stack Pointer Register (SP)

This register is meant to keep track of the end of the stack. However this nothing more than a suggestion to the user, software can use this register as a regular GPR.

Program Counter Register (PC)

This register holds the address of the next instruction to run. Writing to this registers means jumping to other code.

2.2 Background Registers

Background registers can only accessed with the instructions BSTR and BLD.

Table 2.2: List of Background Registers

ID	Mnonic	Descriptive Name	Length in bits
0x0	n/a	Reserved	8
0x1	n/a	Reserved	8
0x2	n/a	Reserved	8
0x3	n/a	Reserved	8
0x4	n/a	Reserved	8
0x5	n/a	Reserved	8
0x6	n/a	Reserved	8
0x7	n/a	Reserved	8
0x8	bpc	Program counter backup	16
0x9	bsf	Segments and flags backup	16
0xA	ipc	Interrupt program counter	16
0xB	is	Interrupt segments	16
0xC	n/a	Reserved	16
0xD	n/a	Reserved	16
0xE	n/a	Reserved	16
0xF	n/a	Reserved	16

Backup Registers

The backup registers are used to backup the state of the CPU (see section 6.2). The foreground registers, segment registers and flags register all have their own backup register. However, most backup register aren't background registers. Only the segment registers, program counter register and flags register have directly accessable backup registers. Note that both segment registers and the flag register share one 16-bit backup register.

Interrupt Registers

The Interrupt registers hold the new state the CPU should jump to when an interrupt is triggered (see chapter 6). Only the segement registers and the program counter have an interrupt register.

2.3 Indirect Registers

Indirect registers are registers that software can't directly read nor write to with any instruction. All the backup registers that aren't background registers fall under this catogory. All the indirect registers can only be written to and read from via the state preservation system (see section 6.2).

Flags Register

The flags register holds multiple flags. These flags are
